

Fixed scenario: $N = 2{,}000$, $m = 250$, $B = 100{,}000$, $R = 150$, $q = 0.15$. Utility peaks at $T^* = 319$ and then declines: once the flip probability saturates, each further bribe adds cost and detection risk but no additional chance of success. $T^*$ is the best point on the evaluated grid rather than an exact argmax; the curve is flat near its peak, so nearby values of $T$ are near-optimal too.
