
Bars are EXPECTED surviving votes over the threshold, so a bar below the line means the mean falls short -- not that the threshold is out of reach. *P* is the exact success probability at full effort, and it shows how quickly that distinction stops mattering: 0.42 where the ratio is 0.97, and numerically zero once the ratio drops below about 0.7. The diamond is the optimal split of a single budget across all three vectors, which is budget-feasible and clears the line in four of the five scenarios.
